I am thankful to the Brazilian Federal Agency for Support and Evaluation of Graduate Education (CAPES) by a doctoral Grant.

## SIMULATION OF A UNIT OF HYDROGEN PRODUCTION THROUGH REFORMING OF BIOGAS

### **Contextualização:**

The emission of the biogas to the atmosphere may contribute to the greenhouse effect. A solution to this problem would be the development of low-cost and high efficiency processes for converting biogas into energy and higher value-added products (1). An efficient technology for the use of biogas for electricity generation would be its use in the production of H<sub>2</sub> for the Proton Exchange Membrane (PEM) fuel cells.

### **Objetivos:**

To simulate a unit of hydrogen production through reforming of biogas obtained from the Jardim Gramacho - RJ landfill for the energy generation using PEM fuel cells.

### **Metodologia:**

The UniSim Software has been used for the simulation of the production of H<sub>2</sub> from the effluent, which has the installed capacity for the annual production of 70.000.000 m<sup>3</sup>. In this approach, the biogas is converted to syngas (H<sub>2</sub> + CO) in a reformer (820°C and 21,3 bar), followed by steps of hydrogen purification: Water Gas Shift - WGS (350°C and 21,3 bar) and Pressure Swing Absorption - PSA (30°C and 21,3 bar).

### **Fundamentação Teórica:**

The use of biogas increases energy efficiency, helping reach the use of resources in a sustainable way, without harming the economic growth. The use of these efficiency technology can generate positive impacts on the environment, public health and economy. Studies (2) estimate the possibility of having an installed capacity of generation of 311 MW of energy, which could supply a population of 5,6 millions of habitants.

### **Resultados e Análises:**

The results showed that it is possible to produce more than 742 kg/hr (17,500 kg/day) at 37.8°C and 354.6 bar. This amount is enough to generate more than 10.3 MW of energy (considering 0.8 Nm<sup>3</sup>/h de H<sub>2</sub>/kWh of produced energy as reference to describe the cell performance of the PEM fuel cell).

### **Considerações Finais:**

Considering the average domestic consumption of electric energy of 0.25kW, the generated hydrogen from the reforming of biogas provided from the Jardim Gramacho RJ landfill would be enough to supply more than 41,000 residencies as an efficient and promising process to energy generation
